

# Python Basics

Ranjan Mondal

Indian Statistical Institute

8th April 2017

# Function

- ▶  $f : a \rightarrow b$ 
  - ▶ Function  $f$  maps from set  $a$  to set  $b$
  - ▶  $b1 = f(a1)$  : Function takes some data  $a1$  and produce  $b1$
- ▶ Multiple return
- ▶ No "call-by-reference" nor "call-by-value" concept
- ▶ Recursion
  - ▶ Three concept: arguments,return,halting conditions
  - ▶ Recursion with no arguments and no return
  - ▶ Recursion with arguments and no return
  - ▶ Recursion with arguments and and return

# File Handeling

- ▶ A file object is created using open function before you read or write.
  - ▶ `f=open(file_name,access_mode)`. This returns a file object if successful else IOError
  - ▶ `access_mode` determines the mode in which the file has to be opened, i.e., read, write, append
    - ▶ `access_mode "r"` : Opens a file for reading only
    - ▶ `access_mode "w"` : Opens a file for writing only. Overwrites the file if the file exists
    - ▶ `access_mode "w+"` : Opens a file for both writing and reading. Overwrites the existing file if the file exists
    - ▶ `access_mode "a+"` : Opens a file for both appending and reading

# Read a file

- ▶ Step 1 :Open a file in read mode. `f=open("file_name","r")`
- ▶ Step 2 :Read
  - ▶ `f.read()` read the whole file into a string.
  - ▶ `f.readline()` read each line and return string
  - ▶ `f.readlines()` read all the lines and return a list of string with all the lines.
- ▶ step 3: `f.close()`

# Write into a file

- ▶ Step 1 :Open a file in write mode. `f=open("file_name","w")`
- ▶ Step 2 :write
  - ▶ `f.write(str)` :Write string str to file
  - ▶ `f.writelines(sequence_of_strings)` : Write the strings to the file
- ▶ step 3: `f.close()`

# Try out

- ▶ write a function that will take a text file name with path and it will print the file line by line .
  - ▶ `func(file_name)`

# Python Data Structures

There four basic Data Structures available in Python.

1. Lists

# Python Data Structures

There four basic Data Structures available in Python.

1. Lists
2. Tuples

# Python Data Structures

3. Dictionary
4. Strings

# Python Data Structures

There four basic Data Structures available in Python.

1. Lists
2. Tuples
3. Dictionary
4. Strings
5. Sets

# Lists

- ▶ An ordered group of items(objects).
- ▶ Does not need to be the same data(object) type.
- ▶ List items is accessed by index.
- ▶ Notation: L=["HI" , "Midnapore" ,123, "CS" ,2.21,0.222]
- ▶ Indexing
  - ▶ Starts from 0 in forward direction.
  - ▶ Starts from -1 in backward direction.

# Methods of Lists

- ▶ `List.append(x)`
  - ▶ `L=[3,'b','c',3,4,3]`
  - ▶ Adds an item to the end of the list
  - ▶ `let L=[3,'b','c',3] ; L.append(4)`

# Methods of Lists

- ▶ `List.count(x)`
  - ▶ `L=[3,'b','c',3,4,3]`
  - ▶ Returns number of occurrences of `x`
  - ▶ `L.count(3)` returns 2.

# Methods of Lists

- ▶ `List.extend(L1)`
  - ▶ `L=[3,'b','c',3,4,3]`
  - ▶ Extend the list by appending all in the given list L1
  - ▶ `L1=[4,3] ; L.extend(L1) ; print L => [3,'b','c',3,4,3]`
  - ▶ Note the difference between `L.append()` and `L.extend()`

# Methods of Lists

- ▶ `List.insert(i,x)`
  - ▶ `L=[3,'b','c',3,4,3]`
  - ▶ Inserts an item `x` at index `l`
  - ▶ `L[0]='Fun with Python '`; `print L => ['Fun with Python','b','c',3,4,3]`

# Methods of Lists

- ▶ `List.remove(x)`
  - ▶ `L=[3,'b','c',3,4,3]`
  - ▶ Remove first occurrence of value `x`
  - ▶ `L.remove('Fun with Python') ; print L ==> ['b','c',3,4,3]`
  - ▶ Try `L.remove(3) ?`

## Try out now

- ▶ Use List as Stack.
- ▶ Can you use List as array(1D,2D,3D,... ) ?

# Tuples

- ▶ Similar to the list data structure
- ▶ Notation: `T=('23',389,'easy')`
- ▶ Tuples are immutable(but lists are). You can't change tuple T like this `T[0]=3` . But in list you can.
- ▶ Tuples are faster than Lists. why ?

# Methods of Tuples

- ▶ `T.count()` , `T.index()`
  - ▶ Same as Lists

# Application of Tuples

- ▶ Faster than lists
- ▶ Protect the data, which is immutable
- ▶ Tuples can be used as keys on dictionaries

# Dictionary

- ▶ Dictionary is a sequence of items.
- ▶ Each item is a pair made of a key and a value
- ▶ Access to the list of keys or values independently
- ▶ Informally we can consider it as hashtable
- ▶ Notation:  $D = \{42:'Hi ', 4:'hello', 2:32\}$ 
  - ▶ `print D[42]` ?
  - ▶ `print D[2]` ?

# Methods of Dictionary

- ▶ `D.values()` Returns list of D's values
  - ▶ `D = {42:'Hi ', 4:'hello',2:32}`
  - ▶ `D.values()` returns `['Hi', 'hello', 32]`
- ▶ `D.keys()` Returns list of D's keys
- ▶ `D.iteritems()` an iterator over the *key, value* items of D
  - ▶ for `k,v` in `D.iteritems()`:  
    `print k,v`
- ▶ `D.has_key(k)` Returns True if D has a key `k`, else False.
  - ▶ `D.has_key('Hi')` returns ?
  - ▶ `D.has_key(4)` returns ?
  - ▶ `D.has_key(2)` returns ?
- ▶ `D.pop(k)` Removes specified key 'k' and return the corresponding value for the key.

# Strings

- ▶ Strings are immutable sequence of characters.
- ▶ Notation
  - ▶ `S = 'Hi, I am at Midnapore'`
  - ▶ `S = "Hi, I am at Midnapore"`
  - ▶ `S = '''Hi, I am at Midnapore'''`
  - ▶ `S = """Hi, I am at Midnapore"""`
  - ▶ `""" S= My name is "ranjan" """`
- ▶ Indexing
  - ▶ Starts from 0 in forward direction.
  - ▶ Starts from -1 in backward direction.

# Methods of Strings

- ▶ `S="python is fun"`
- ▶ `S.count()` Return the number of non-overlapping occurrences of substring `sub` in string `S`.
- ▶ `S.isdigit()` Return `True` if all characters in `S` are digits else `False`.
- ▶ `S.split(sep)` Return a list of the words in the string `S`, using `sep` as the delimiter string. example: `S.split(" ")`
- ▶ `S.find(s)` Return the lowest index in `S` where substring `s` is found. Return `-1` on failure.
- ▶ `S.replace(old,new)` Return a copy of string `S` with all occurrences of substring `old` replaced by `new`.
  - ▶ `S=S.replace('python','CS')`
- ▶ operators `+` and `*` to create new strings.
  - ▶ `S="hello"`
  - ▶ `S=S+"everybody."+"How are you?."`
  - ▶ `S=S*2`
  - ▶ `print S`

# Sets

- ▶ Sets are constructed from a sequence.
- ▶ Cannot have duplicated items.
- ▶ Notation and Example
  - ▶  $a = \text{set}([1, 2, 3, 4])$
  - ▶  $b = \text{set}([3, 4, 5, 6])$
  - ▶  $c = a | b$  (Union)
    - ▶  $c$  is a Union of  $a$  and  $b$ . i.e  $[1, 2, 3, 4, 5, 6]$
  - ▶  $c = a \& b$  (Intersection)
    - ▶  $c$  is a Intersection of  $a$  and  $b$ . i.e  $[3, 4]$
  - ▶  $a < b$  returns True if  $a$  is a subset of  $b$ .
  - ▶  $a - b$  is a Difference from set  $a$  with  $b$ .
  - ▶  $a \hat{ } b$  is a Symmetric Difference between  $a$  and  $b$ .

THANK YOU
